The Development of the Neural Crest and the Migration of Neural Crest Cells (NCCs) in the Embryos of Various Vertebrates

By: Hall, Brian K. Barnes, M. Elizabeth  Keywords: neural crest cells

Object is a digitized image line drawings that depict the formation of neural crest cells in vertebrates. Image has six sub images, which depict six stages, labeled (a) through (f), of the neural plate as it folds to form the neural tube, neural crest cells, and a sheet of extoderm. Arrows between the six subimages indicate developmental processes for different taxa. The path from (a) to (b) to (c) represents the process in rats. The path (a) to (b) to (d) to (f) represents the process in birds. The path (a) to (b) to (e) to (f) represents the process in amphibians.

This diagram shows how NCCs migrate differently in rats, birds and amphibians. The arrows represent both chronology of NCCs migration and the differential paths that NCCs follow in different classes of animals. The solid black portion of each illustration represents the neural crest, and the large black dots in (c) and in (f) represent the neural crest cells. The speckled sections that at first form a basin in (a) and then close to form a tube in (f) represent the neural ectoderm. The solid white portions represent the epidermal ectoderm. During the neurula stage of all vertebrate embryos (a), the neural crest is located in two places on the neural plate. As the neural tube forms (b), a process called neurulation, the neural crest moves with the folding plate as it forms the junction between the neural and epidermal ectoderm. NCCs migrate differently in different classes of vertebrates (c-f). For instance, in rats (c), the NCCs migrate away from the neural crest before neurulation completes and while the neural fold is still open. In birds (d and f), neural crest cells do not migrate until the neural fold closes. In amphibians (e and f), the neural crest cells migrate after neurulation completes, and only after the cells have accumulated above the neural tube. Subsequently, NCCs will all migrate down their specialized pathways and diversify into the several sub-types of NCCs.
