Ericsson Method of Sperm Separation

By: Blight, Alyse

In 1973, Ronald Ericsson developed the Ericsson method, which is a technique used to separate human male sperm[6] cells by their genetic material. Ericsson, a physician and reproduction researcher, developed the method while conducting research on sperm[7] isolation in Berlin, Germany, in the early 1970s. He found that the sperm[8] cells that carry male-producing Y chromosomes move through liquid faster than the cells that carry female-producing X chromosomes. As a result of his findings, Ericsson suggested suspending a semen[3] sample in a viscous liquid made from albumin protein, and collecting only sperm[8] that quickly pass through the liquid. Shortly after Ericsson described his method, researchers demonstrated that it was effective for sex selection. However, later studies contested those results.

Despite that, the Ericsson method was still utilized by couples in 2018 as a means of sex selection and was the first sperm[8] separation technique used in combination with artificial insemination[6] to enable people to select the sex of their children.

Humans have two sex chromosomes, one passed down from each parent, which affect their biological sex characteristics. People with two X chromosomes are biologically female, while people with one X and one Y chromosome are biologically male. Since females have two X chromosomes, they are able to contribute only an X chromosome to their offspring. Males have both X and Y chromosomes and can therefore contribute either an X or a Y chromosome to their offspring. Therefore, male sperm[8] cells are responsible for determining the sex of an embryo. If the male sperm[8] cell that fertilizes a female egg[9] contains a Y chromosome, the embryo is male. If the male sperm[8] cell that fertilizes a female egg[9] contains an X chromosome, the embryo is female. The mechanism affecting sex ratio, or the ability of sperm[8] cells to move throughout the female reproductive tract to reach and fertilize an egg[9], is seen in their capacity for swimming. A sperm's swimming ability can indicate how successfully the sperm[8] can reach and fertilize an egg[9].

During the late twentieth century, emerging research suggested a difference between chromosome-bearing sperm[8] cells and Y chromosome-bearing sperm[8] cells. In the 1960s, Landrum B. Shettles, a researcher and physician who specialized in human reproduction, claimed that there were physical differences between the two types of male sperm[8] cells. Shettles's idea stimulated interest in the field of research for preconception sex predetermination.

In its early development, the Ericsson method's primary use was not for preconception sex selection. In December 1974, Ericsson patented his method and included the objectives of his sperm separation technique, which he listed in order of importance. Ericsson's primary objective was to provide a process for separating human male semen[8] samples into sperm[8] cells that have an enriched concentration of sperm[8] cells carrying Y chromosomes. Next, he listed using the enhanced Y chromosome-bearing sperm[8] fraction for artificial insemination[6] to increase the likelihood of male offspring, and did not place actions on how to do so in the patent. However, artificial insemination[6], the process in which sperm[8] is injected directly into a female's uterus for fertilization[14], was already a common practice at the time Ericsson patented his method. In order for someone to use the Ericsson method for preconception sex selection, couples would need to inject the Y chromosome-bearing sperm[8] cells directly into a female's uterus[10], with an egg[9] being a syringe after the sperm[8] cells are separated through the albumin medium. In his patent, Ericsson briefly mentioned that the method could be used for family planning[15]. He claimed that a strong desire to have a child of a particular sex often causes couples to have many children until their favored sex is achieved, and that utilizing his method of sperm[8] separation for preconception sex selection would therefore reduce the society's chance of possible overpopulation.

Two years after its initial development, a clinical trial tested the Ericsson method for preconception sex selection. Prior to that clinical trial, studies had shown that the method was effective for collecting semen[8] samples with high concentrations of Y chromosome-carrying sperm[8] cells. But there was no evidence that those samples successfully created male offspring because they had not yet been tested using artificial insemination[6], as there were still X chromosomes present in the sample. In 1975 physician Paul Dmowski, who specialized in obstetrics and gynecology and his team of researchers at the University of Chicago's Pritzker School of Medicine in Chicago, Illinois, began a clinical trial to test whether the separated samples produced by the Ericsson method affected the sex ratio of human offspring. During that initial clinical trial, physicians successfully impregnated seven women using artificial insemination[6] with sperm[8] cells that were separated by the Ericsson method. Of those seven, five women delivered male infants. The researchers involved in the initial clinical trial determined that when sperm[8] cells are separated using the Ericsson method and artificially inseminated for conception[16], there is an increased chance of producing male offspring.

Since that initial clinical trial, further studies have supported the effectiveness of the Ericsson method. In 1976, Ericsson began a clinical trial in collaboration with Ferdinand Beernink, an obstetrician and gynecologist at the University of Michigan Medical Center in Ann Arbor, Michigan. Ericsson then separated the sperm[8] cells from twenty-one healthy males. Even after following Ericsson's methods precisely, the researchers failed to show that Ericsson's albumin-medium sperm[8] separation produced an enrichment of sperm[8] cells that carried Y chromosomes. In fact, the results produced a slightly increased concentration of X chromosome-bearing sperm[8] cells in the sample collected at the bottom of the albumin column, which contradicted Ericsson's original finding. The 1976 study did not use the separated sperm[8] samples for artificial insemination[6] to see if the sex ratio was affected. However, the results did not confirm Ericsson's results from his initial study.

In 1979, another study published in Human Reproduction attempted to make definitive conclusions on the effectiveness of the Ericsson method. That study replicated the original methods exactly, and also addressed the alterations made in previous studies that did not confirm Ericsson's initial results. The experiment was conducted at Taichung Veterans General Hospital's Department of Obstetrics and Gynecology in Taiwan. The researchers examined sperm[8] samples from twenty-one healthy males. Even after following Ericsson's methods precisely, the researchers failed to show that Ericsson's albumin-medium sperm[8] separation produced an enrichment of sperm[8] cells that carried Y chromosomes. In fact, the results produced a slightly increased concentration of X chromosome-bearing sperm[8] cells in the sample collected at the bottom of the albumin column. The 1979 study did not use the separated sperm[8] samples for artificial insemination[6] to see if the sex ratio was affected. However, the results did not confirm Ericsson's results from his initial study.

Despite the inconclusive data that both supports and invalidates the Ericsson method, the method is still utilized for sex selection at Gametec Limited. As of 2018, Ericsson is the president of Gametec Limited, a company he created that has exclusive access to his patented method of sperm separation using albumin columns. While the company’s headquarters are in Alzada, Montana, the laboratory performed, called Sperm Centers, which offer the Ericsson albumin method both in the US and internationally. According to the Gametec Limited website, thousands of children have been born using the Ericsson method, but the success rates for couples that have achieved their desired sex are not advertised directly. Instead, the website provides twelve citations of scientific papers that discuss the development of the method and data from published clinical trials that support its use. Gametec Limited claimed their Sperm Centers have demonstrated an 86 percent success rate for producing a male offspring. Since then, there have been no additional amendments from the company.
